

$$\times u_1^1 \dots u_n^1 = r^1$$

$$\times u_1^m \dots u_n^m \neq r^m$$

x_c, v_1, \dots, v_n - choice var.

game moves to different eqs in different eq.

x_i, v_1, \dots, v_n - contrib. var

game changes this on going to one of the eqs.

Claim:

On each path in t that leads to a leaf there are only

- a) main choice variables or
- b) main contributing variables
- c) nil variables (on leaves)
- d) constants

(provided that no transformation can be applied).

Estimation on the number of occurrences:

- c) at most once
- d) at most depth(rhs)
- b) at most depth(rhs)
- a) the number of (in)equations

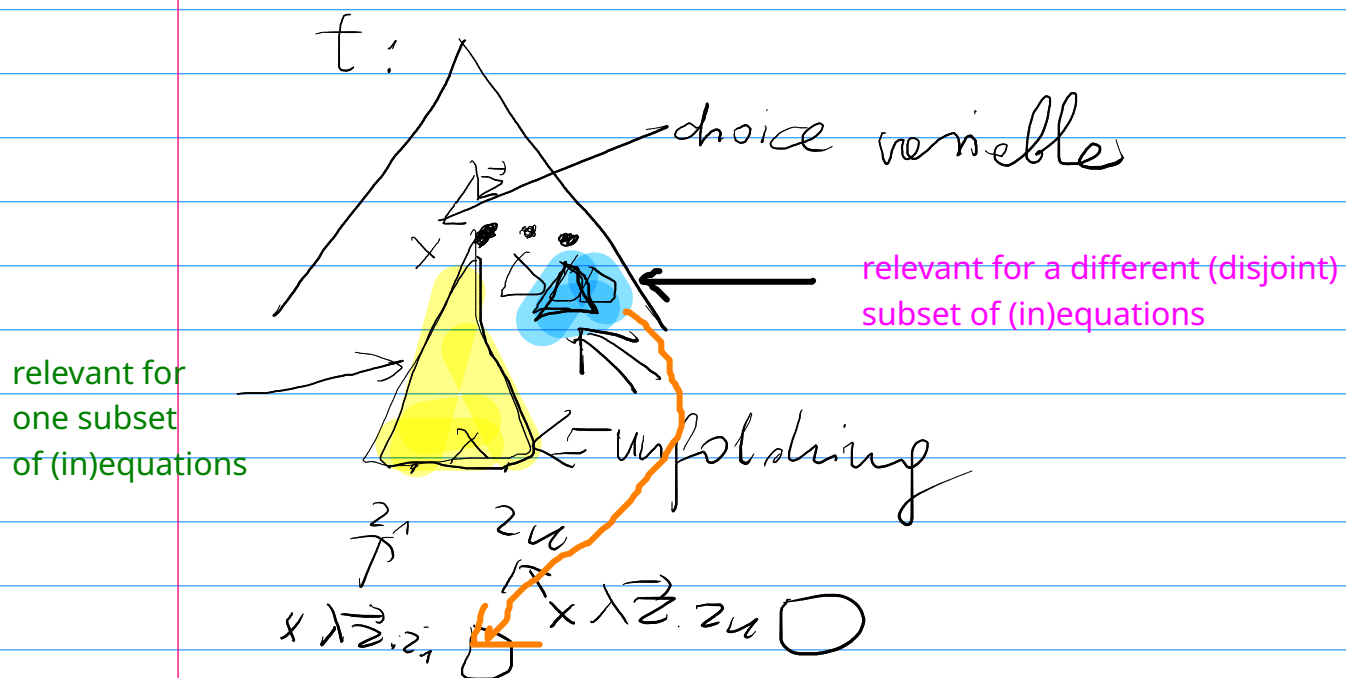

Suppose, we do not have the possibility to apply a transformation.

x - is an (occurrence of) variable that

* does not contribute

* is not a choice variable

Once there are no transformations possible, choice variables that are not contributing occur at most once for each (in)equation.

For a uniform variable
